EXECUTIVE SUMMARY

In July 2006, Gibbs & Olson, Inc. presented to the City (City) Phase I of the Kelso Stormwater Management Plan (SMP). Phase I included the delineation of the stormwater basins within the city limits and provided a SMP for drainage within Basin 1 of the City. The Phase I SMP included inventory of the existing structures and pipes, evaluation of the materials and function of the system, and recommendations for the improvement to the city's Phase I system. In May of 2007, Gibbs & Olson, in conjunction with the City, began Phase II of the SMP, which includes five basins, Basins 10 through 14. A map of the city basin delineations was included in the Phase I report.

As in Phase I, Phase II of the SMP identifies deficiencies and recommends improvements for the following three elements of the storm drainage system:

- Pipe capacities
- Pipe materials
- Structure access and connections

Development of the SMP included the following steps:

- Preparation of an inventory of the existing stormwater collection system
- Modeling of the existing collection system in Phase II
- Identification of areas of insufficiency
- Preparation of a Capital Improvement Plan (CIP) for recommended improvements

Stormwater Collection System

Phase II includes five Basins, Basins 10, 11, 12, 13 and 14, as shown on Figure A in Appendix A. The City developed a numbering scheme for identifying the existing structures within Phase II, surveyed in the coordinate location (northing and easting), structure rim elevation and documented the structure type, the number of pipes, size and type of pipes, and measure downs within the structure. Gibbs & Olson, Inc. then entered data based on the structure information documented in the field by City personnel. An overall data file has been created based on

compilation of the data. Structure and pipe information was entered into StormCad (Haested Methods) to develop system flows utilizing the Rational Method and develop pipe capacities. Each basin was modeled separately and the overall area for each basin was divided into individual areas corresponding to the number of inlet structures.

System Deficiencies

Modeling for system deficiencies was conducted for each basin in Phase II using a 25-year storm analysis. Individual system flows and capacities for each basin can be found in Appendices B-F. Modeling identified capacities for the corresponding systems, together with individual pipe capacities and identified areas where existing system capacity was insufficient for modeled storm flows. In some locations, pipe material was more of an influence in capacity deficiency than pipe diameter.

A Capital Improvement Plan (CIP) is developed incorporating recommended improvements and associated cost estimates. Summary of the CIP is provided in Chapter 3 and at the end of each basin analysis in Appendices B-F.

CHAPTER 1

INTRODUCTION

1.1 PURPOSE

In response to the 1987 Amendments to the Clean Water Act (CWA), the U.S. Environmental Protection Agency (EPA) developed Phase I of the National Pollutant Discharge Elimination System (NPDES) Stormwater Program in 1990. The Phase I program addressed sources of stormwater runoff that had the greatest potential to negatively impact water quality. Under Phase I, EPA required NPDES permit coverage for stormwater discharges from medium and large municipalities (communities with populations greater than 100,000). Following the Phase I regulations, Phase II of the NPDES Stormwater Program was implemented which required communities with populations greater than 10,000 to comply with the NPDES regulations. With a population of approximately 11,950, the City of Kelso fell within these Phase II parameters and is now covered under the NPDES Western Washington Phase II Municipal Stormwater Permit (Permit). The Permit requires the City to develop a municipal storm sewer map. This report continues to develop this map and the associated Capitol Improvements Program (CIP) for the City.

1.2 SCOPE OF PLAN

This SWP is intended to be the guiding document regarding the management of stormwater, quality and quantity, within the direct control of the City of Kelso. Operation and Maintenance (O&M) outlines will be identified in the SWP as guiding principles for the City's activities in the stormwater arena. A Capital Improvement Plan (CIP) for Phase II has been developed for future City budget planning considerations.

1.3 GOALS AND OBJECTIVES

Goals

The goal of this plan is to:

1) Develop a continuous and comprehensive program for managing surface water and recognizing subsurface drainage contributions in Kelso that prevents property damage and meets or exceeds water quality standards, and;
2) Identify the existing system and its inadequacies and recommend improvements to the system in Basins 10-14. *(Phase I completed July 2006).*
3) Develop a procedure to inventory and analyze the remaining Phases within the City of Kelso city limits.

Objectives

The following objectives are designed to accomplish the above goals:

1) Develop stormwater basin boundaries within the City of Kelso city limits *(completed July 2006)*;
2) Develop a stormwater system inventory that provides a horizontal and vertical relationship together with pipe sizes for all known storm systems within the City;
3) Outline the current existing city conditions with respect to stormwater area characteristics, city policies and regulations, and how the system works;
4) Develop comprehensive maps of the City's drainage system;
5) Analyze the existing drainage system;
6) Develop a Capital Improvements Program;

CHAPTER 2

PHASE II SYSTEM ASSESSMENT

2.1 GENERAL

The current Phase II system is a combination of primarily public with some private systems. The City of Kelso owns and maintains the system in the public right-of-way together with some easements that cross private property.

Private systems were found in several locations within Phase II, consisting of catch basins, manholes and piping. These systems were identified on the individual basin maps, but specific information for some areas of this study was not obtained due to the inability to access the structures on private property.

2.2 HYDROLOGY

A plan of the Phase II system of catch basins and manholes has been mapped and is included in the report in Appendix A. Field data for pipe size, invert elevations (IE), pipe materials, as well as lengths, have been recorded. This Phase includes five basins with basic flow modeling performed using StormCad by Haested Methods to determine where potential flow problems are likely to exist, and to aid in identifying capital improvement projects. StormCad calculates flow (Q) utilizing the Rational Method, Q=CIA. Each catch basin or inlet was assigned an inlet area (in acres) developed by dividing the overall area by the number of inlets. In most instances, the time of concentration for each inlet was entered as five minutes for the Phase II Basin Areas. The rainfall intensity (I) for the modeling was developed based on the 25-year, 24-hour rainfall total as listed in the Stormwater Runoff Control Guidelines for the Longview-Kelso Urban Area. Individual runoff coefficients (C) were selected for each area based on the existing City Zoning Map. The coefficients for the types of drainage area are listed with a range and the median value was used. Phase II basin had a wide range of use from single-family residential to multi-family and commercial. The values for the runoff coefficients used in the runoff calculations are listed in Table 2A.

Land Use	Listed Range for C	Value Used
Single Family Residential	0.3-0.5	0.40
Multi-Family Residential	0.40-0.75	0.60
Commercial: Town Center Special Retail Major Retail	0.70-0.95	 0.80 0.90
Open Space: Rail Yard	0.20-0.35	0.27

Table 2A Runoff Coefficients, C

2.3 SYSTEM ISSUES

As stated previously, a system inventory of Phase II was conducted in a cooperative effort between the City of Kelso and Gibbs & Olson, Inc. The City of Kelso numbered the system structures, surveyed in the coordinate locations using the Washington State Reference Network, and gathered the system information such as pipe sizes and types, along with measure down information for determining invert elevations. A listing of all points gathered for Phase II and a listing of all unused points are provided in Appendix G. Using the structure rim elevation and the measure down data gathered by the City of Kelso, invert elevations were calculated and applied to the pipes entering or exiting a structure. During the analysis of the data for the five basins, several issues became apparent with the City's system. Each of the five basins is discussed in further detail in Appendices B-F.

Several catch basins had pipe leading to a main line pipe with no identified downstream structure connection, and were assumed to be blind connections. Due to the constraints of the modeling program, blind connections cannot be added to the system, and therefore, junctions were added where a blind connection was apparent. For ease of modeling, where two blind connections enter within the same proximity, the blind connections were added at the inserted junction location, using the prefix J in the numbering system for easy identification. In most cases, the City should assume the blind connections occur at 90-degrees to the trunk line pipe. It is recommended that wherever a junction is present, the City perform additional field investigation to determine if a structure exists below the

pavement surface, or if a blind connection actually exists. This investigation would most likely need to occur by television analysis of the system. In addition, some catch basins had smaller diameter pipe entering a basin with no known upstream structure. For the purpose of the model, these pipes were assumed as private roof or yard drains and were not included in the model. (See original field note data for additional information.) However, the area draining the pipe was accounted for in the overall analysis.

Pipe size: The first system issue identified is the presence of small diameter pipe, that is, pipe less than 12-inches in diameter. Approximately 47% of the City's system is comprised of pipe with diameters less than 12-inches. Table 2B shows the pipe compilation by size and material. The small diameter pipe, in conjunction with the relatively flat pipe slopes, severely inhibits the capacity of the piping system due to the reduced flow capacity. A preliminary recommendation is to remove any trunk lines with piping less than 12-inches in diameter and replace with a minimum of 12-inch diameter pipe.

Pipe Size (inches)	Concrete (ft)	CMP (ft)	PVC (ft)	Clay (ft)	HDPE (ft)	Ductile Iron (ft)	Total (ft)	Percentage
4	4	0	147	0	0	0	151	0.32%
6	3,944	0	1,180	197	0	12	5,333	11.35%

48	726	94	0	0	0	0	820	1.74%
60	127	0	0	0	0	0	127	0.27%
Total (ft)	**30,760**	**4,922**	**7,111**	**2,694**	**1,269**	**247**	47,003	100.00%
Percentage	65.44%	10.47%	15.13%	5.73%	2.70%	0.53%	100.00%	

Table 2B Phase II Pipe Totals

Pipe Material: The City's system is comprised of multiple material types, including concrete, polyvinyl chloride (PVC), clay, high density polyethylene (HDPE) and corrugated metal pipe (CMP). The majority of the City's system (65%) consists of concrete pipe. Many issues in the City's system can be attributed to the degradation of concrete pipe. In addition, 10% of the City's system is comprised of CMP, which inhibits the flow of stormwater through the system. The majority of CMP is located in Basins 11 and 12 which drain the area around the Three Rivers Mall.

System Maintenance: The final contributing issue to the City of Kelso's stormwater system is maintenance. During the inventory of structures and pipes, several notes were made in regards to cleaning a structure or pipe connection. Cleaning of a structure took place where needed to obtain existing data, and it is recommended the system continue to be cleaned on a regular basis to maintain the function of the system until recommended improvements can be made. An order of precedence for cleaning and improvements is listed in Chapter 3.

2.4 CONCLUSIONS

Reviewing Basins 10 through 14, the most prominent issue for the functioning of Phase II is the presence of small diameter pipe and the lack of available pipe slope. Providing positive slope for those identified with negative slope is the first issue to be addressed. For those pipes with positive but relatively flat slopes, increasing the pipe size will provide additional capacity for the system. A notable issue to contend with is the lack of ground cover for the piping system. In some cases, providing increased slope and/or larger pipe sizes may not be feasible due to the lack of ground cover over the pipes. In these instances, it may be necessary to utilize a specialized pipe such as an arch pipe, or install two or more pipes of smaller diameter in parallel to provide the capacity required. A detailed engineered design of specific pipe replacements will be required that takes into account ground cover, existing invert elevations of adjacent pipes, other underground utilities and the surrounding environment.

CHAPTER 3

RECOMMENDATIONS

3.1 GENERAL:

With respect to storm water, the City's current system complies with existing local and state requirements, with regular maintenance being the main ongoing expense. It should be noted that storm water is a new evolving field which is in its infancy. Driven by federally mandated changes, that are being governmentally implemented by the State of Washington Department of Ecology (DOE), the existing standards will be evolving and changing over the next decade.

This stormwater plan for Phase II, together with the following recommendations, represents a General Plan which will provide a proactive response for the citizens of Kelso, together with a comprehensive inventory of the City's existing stormwater infrastructure, to aid in a smooth and cost effective transition to the storm water demands of 2013 and beyond.

3.2 SYSTEM UPGRADES

The Phase II inventory for storm water piping and devices represents the best available information at this time. As ongoing piping and devices are expanded or upgraded into the system, the new installations need to be added to the existing inventory. Additionally, should pre-existing conditions be found that are not inventoried, these should be appended into the City's inventory.

Over 47% of the Phase II existing system is comprised of pipes with diameters less than 12-inches (see Chapter 2, Table 2.B). Many of these lines are single pipes connecting into a trunk line, and are not causing a significant problem to the system flow. However, it is recommended that any new pipe installed be a minimum of 12-inches in diameter. Overall, 34,870 linear feet of pipe (74%) were identified as undersized and 21,834 LF (46%) were identified as trunk line pipes to be upgraded. Table 3A shows the breakdown of recommended pipe upgrades per Basin and pipe size.

Pipe Size	10	11	12	13	14	Total
12-inch	0	0	0	0	2,138	**2,138**
18-inch	881	0	0	1,558	1,350	**3,789**
24-inch	1,459	382	0	547	510	**2,898**
30-inch	890	601	0	272	231	**1,994**
36-inch	1,253	707	0	0	0	**1,960**
42-inch	0	751	0	269	0	**1,020**
48-inch	0	1,050	0	300	0	**1,350**
54-inch	319	0	521	513	0	**1,353**
60-inch	1,946	376	1,281	0	0	**3,603**
66-inch	512	0	853	0	0	**1,365**
90-inch	0	0	0	364	0	**364**
Total	**7,260**	**3,867**	**2,655**	**3,823**	**4,229**	**21,834**

Table 3A Pipe Upgrades

The modeling results for the 25-year storm indicate the majority of the system in Phase II is undersized, and should be upsized according to the recommendations in the individual Basin assessments in Appendix B. However, it should be noted much of the system had hydraulic grade lines at or below the existing ground elevation, and while full, may not be creating a major flooding problem.

3.3 CAPITAL IMPROVEMENTS

Appendices B through F contain information on Basins 10 through 14 and recommended improvements. A compilation of the estimated budget for completing all the pipe upgrades and repairing the surface to existing conditions is shown in Table 3B. Since this is a storm water project in the City's street right of way, sales tax is not applied to the estimate. The total Preliminary Opinion of Probable Cost for the identified improvements is $4,715,000. A detailed breakdown of cost is included in the Table 4 for each basin summary. This cost is based on contracting the work to be done by other than City of Kelso forces.

Basin	TOTAL
10	$1,598,345
11	$915,995
12	$938,050
13	$766,500
14	$494,620
Total Phase II	**$4,713,510**

Table 3B Preliminary Opinion of Probable Cost, Phase II

It is unlikely the City of Kelso will have the estimated budget to complete all the recommended upgrades to the system at the same time, as listed in this report. Therefore, a guideline for order of precedence for the CIP has been developed and is suggested as follows:

1. Clean catch basins and storm drain manholes to verify pipe inverts;
2. Clean and television storm drain pipes to determine if blockages are encountered;
3. Replace corrugated metal and clay/terracotta pipes with HDPE pipe such as ADS N-12 or similar;
4. Upgrade storm drain pipes on trunk lines to sizes recommended to handle flow from side systems and to provide additional storage during larger storm events;
5. Upgrade storm drain pipes on side streets to sizes recommended.

These recommendations are based on a planning level assessment only. There may be physical constraints that make it impossible to install the large pipes recommended for upgrading the system. A detailed engineered design of the proposed system will be required, which takes into account the existing surrounding environment. The individual and overall system budget estimates have been developed based on the cost to remove and replace the pipes with the sizes as shown, and to repair the existing surface to its current condition. Consideration should be

given to the shallow cover and other utilities within the City's right of way which may require additional engineering solutions and add unknown costs to those provided in this report.

Basin 10

BASIN 10

SYSTEM ASSESSMENT

Basin Description: Basin 10 consists of the structures along Grade Street, 1st Avenue and the north boundary of Basin 1, from Church Street south to Chestnut Street. It drains an area between the bank of the Cowlitz River dike on the west and the bank of the Coweeman River to the east, from Church Street to the north boundary of Basin 1. Figure 10.1 shows an aerial photograph of Basin 10. It contains 217 structures (148 catch basin, 8 curb inlets, 61 manholes and 38 assumed connections), the majority of which are between 1st and 5th Avenues and Oak and Alder Streets. The outlet for the Basin 10 model is at node 4138 in Grade Street. The runoff from Basin 10 flows from 4138 into a 36-inch pipe that crosses Grade Street and continues south along 13th Avenue, eventually discharging to the Coweeman slough. Due to high water elevations and confined entry restrictions, field data was not obtained for this run. It is recommended further field investigation take place so the remainder of the system be modeled.

The total drainage area for Basin 10 is 108.9 acres. However, approximately 31% of the basin area, 33.5 acres, was eliminated from this phase due to insufficient data to complete the modeling of the existing system. The land use for the 74.5 acres included in the model is approximately 8% single family residential, 37% multi-family residential, 18% special retail, 6% major retail, 29% town center and 2% open space. See Figure 10.2 for the land use areas in Basin 10.

System Modeling: Table 10.1, System Summary, lists the structure information and connections, along with total flows and capacities. Figures 10.3-1 and 10.3-2 show a schematic of the structure locations and piping layout. As stated in Chapter 2, junctions were entered into the model where blind connections were assumed to occur, using the prefix J in the numbering system for easy identification.

Other assumptions were made in the modeling, such as interpolating an invert or rim elevation when junctions were added to the system. The field data for points 4067,

4068 and 1216 indicate each had pipes to the east, toward the City parking lot, matching the City's schematic. However, no structures were field located to complete the connection between 4067 and 4068. Therefore, junctions J-10-34 and J-10-35 were inserted, matching the City's schematic, and pipes inserted connecting 4067 and 4068, with slopes assumed based on the invert out of 4067 and the invert in at 4068. For modeling purposes, point 1216 was assumed to connect at J-10-35, matching the field data for the pipe exiting this structure. It is recommended that additional investigation be performed to determine if structures exist at J-10-34 and J-10-35.

There are several locations where field data indicates the system flow (based on pipe inverts) is heading in a particular direction, but the system could not be connected due to a missing structure, such as at 5th Avenue and Oak Street. For modeling purposes, a junction was inserted to complete the system. It is recommended that additional field investigation be performed to determine if a structure exists at the intersection of 5th Avenue and Oak Street, identified in Basin 10 as J-10-17.

As seen in Table 10.1, the majority of pipes with insufficient capacity (50%) are less than 12-inch in diameter. Utilizing the current slopes, the majority of pipes less than 12-inch in diameter will gain capacity by upsizing to 12-inch HDPE pipe. The majority of pipes along Grade Street, Ash Street and Pacific Avenue (P-10-100 through P-10-127, considered the trunk line) have slopes less than 0.005 ft/ft, severely inhibiting the capacity of the system. Increasing these pipes from the existing to HDPE in the diameter listed in Table 10.3, keeping the same slope, will provide increased capacity in the system.

SYSTEM ISSUES

Pipe size: The first system issue identified for Basin 10 is the presence of small diameter pipe, that is, pipe less than 12-inches in diameter. Approximately 50% of the system is comprised of pipe with a diameter less than 12-inches. Table 10.2 shows the pipe compilation by size and material. The small diameter pipe severely inhibits the capacity of the piping system due to the reduced flow capacity. A preliminary recommendation is

to remove any trunk lines with piping less than 12-inches in diameter and replace with a minimum of 18-inch diameter pipe.

Pipe Material: Basin 10 is comprised of five modeled material types: concrete, CMP, PVC, clay and HDPE. The majority of the system, (90%) consists of concrete and clay, with the remaining 10% comprised of PVC, HDPE and CMP. Both concrete and clay pipe are similar in properties, with a relatively low Manning's coefficient. However, both concrete and clay piping are rigid materials that provide movement only at the joints, and are susceptible to separation, fracture or breakage in the pipe if ground movement occurs. Typically, the most common failure in older concrete pipe occurs at the joints as the rubber gaskets become brittle and disintegrate, providing an opportunity for the pipe to separate. Overtime, this can lead to deposit of unwanted material in the pipe and degradation or failure of the pipe. Material in the pipe opening blocks the path of flow for storm water, making it less effective. In addition, the life expectancy of concrete pipe is approximately 40-years versus HDPE which has a projected life span in excess of 100 years. Material such as HDPE is more flexible and less likely to degrade overtime, and for this reason it is recommended replacement of any concrete or clay pipe be completed with HDPE.

System Maintenance: The final contributing issue to the City of Kelso Basin 10 storm water system is maintenance. During the inventory of structures and pipes, several notes were made in regards to cleaning a structure or pipe connection. The inability to obtain specific inventory data for the pipes and structures along 13th Avenue resulted in the need to truncate the modeling at structure 4138, the last structure with sufficient data for running the model. Cleaning of many structures took place to obtain existing data, and it is recommended the system continue to be cleaned on an annual or semi-annual basis to maintain the function of the system until recommended improvements can be made.

RECOMMENDATIONS

System Replacements: It is recommended at a minimum that the main pipes down 1st, Pacific, and 5th Avenue, and Ash and Grade Streets (considered trunk line pipes) be replaced with HDPE pipe in the diameter size listed in Table 10.3. This would allow for increased pipe capacity and act as storage for the system should downstream tail-water conditions occur. Many of the smaller lines in the system are connecting into the trunk line and do not appear to be causing a significant problem to the system. However, it is recommended that any new or replaced pipe be composed of HDPE at a minimum diameter of 18-inches. A total of 7,260 LF of trunk line pipes are recommended for upsizing.

Capital Improvements: The estimated budget to upgrade from the existing pipe sizes to the pipe sizes listed is approximately $1,600,000, as shown in Table 10.4. This cost is based on contracting the work to be done by other than City of Kelso forces, and includes the cost for repairing the surface to the existing conditions.

Operation and Maintenance: A guideline for order of precedence for the CIP has been developed such that budget consideration can be included and is suggested as follows:

1. Clean catch basins and storm drain manholes;
2. Clean and television storm drain pipes to determine if blockages are encountered;
3. Replace concrete and clay pipes with HDPE pipe such as ADS N-12 or similar;
4. Upgrade storm drain pipes on trunk lines to sizes recommended to handle flow from side systems and to provide additional storage during larger storm events;
5. Upgrade storm drain pipes on side streets to sizes recommended, and eliminate as many blind connections as possible during the improvement process.

These recommendations are based on a planning level assessment only. There may be physical constraints that make it impossible to install the large pipes recommended for upgrading the system. A detailed engineered design of the proposed system will be required, which takes into account the existing surrounding environment. The individual and overall system budget estimates have been developed based on the cost to remove

and replace the pipes with the sizes as shown, and to repair the existing surface to its current condition. Consideration should be given to the shallow cover and other utilities within the City's right of way which may require additional engineering solutions and add unknown costs to those provided in this report.

Kelso Stormwater Management Plan
Phase II
Summary Legend

Legend

	System Flow > Pipe Capacity
	Ground elevation interpolated from nearest structure
	Invert elevation interpolated from upstream and downstream nodes
-0.02	Negative slope based on data provided
J	Junction
O	Outlet
Conc.	Concrete
T-cotta	Terracotta
DI	Ductile Iron
PVC	Polyvinyl Chloride
HDPE	High Density Polyethylene
CMP	Corrugated Metal Pipe
1000's	Catch Basins
4000's	Manholes or Curb Inlets
NDA	No Data Available

Appendix C

Basin 11

BASIN 11

SYSTEM ASSESSMENT

Basin Description: Basin 11 consists of the structures in the area of the Three Rivers Mall. It drains an area bound between Grade Street along the southwest edge, Manasco Drive and Interstate 5 (1-5) along the southeast edge, and Basin 12 to the north. Figure 11.1 shows an aerial photograph of Basin 11. The majority of structures within this basin are located outside City right-of-way and are privately maintained. The outlet for the Basin 11 model is at node 4358 in Grade Street. The runoff from Basin 11 flows from 4358 into a 36-inch pipe that crosses Grade Street and continues south along 13th Avenue, eventually discharging to the Coweeman slough. Due to high water elevations and confined entry restrictions field data was not obtained for this run. It is recommended that further field investigation take place so the remainder of the system be modeled. The total drainage area for Basin 11 is 40.64 acres, and the land use is 100% Major Retail. See Figure 11.2 for the land use areas in Basin 11.

System Modeling: Table 11.1 lists the structure information and connections, along with total flows and capacities. Figure 11.3 shows a schematic of the structure locations and piping layout. As stated in Chapter 2, junctions were entered into the model where blind connections were assumed to occur using the prefix J in the numbering system for easy identification. Insufficient field data was able to be obtained for catch basins 1142, 1176, 1177 & 1179 and manholes 4049 and 4050. Therefore, As-Built Construction drawings for Top Foods were used to input pipe data to connect these structures to the system.

Other assumptions were made in the modeling, such as interpolating an invert or rim elevation when junctions were added to the system. The field data for catch basin 1193 indicates an additional pipe was entering this structure. However, catch basin 1395 had four unaccounted for pipes, none of which could be connected to 1193. It was assumed that catch basin 1395 connects to the system in Manasco Drive to the east. It is recommended that additional investigation be performed to determine how this catch basin connects to the system.

As seen in Table 11.1, a significant number of pipes with insufficient capacity (19%) are less than 12-inch in diameter. Utilizing the current slopes, the majority of these pipes will gain capacity by upsizing to 12- or 18-inch HDPE pipe. Pipes P-11-100 to P-11-108 are 32-inch to 48-inch in diameter, but have insufficient slope, and are undersized based on the modeled amount of flow in the system. Increasing these pipes from the existing to HDPE in the diameter listed in Table 11.3, keeping the same slope, will provide increased capacity in the system.

System Issues

Pipe size: The presence of small diameter pipe, that is, pipe less than 12-inches in diameter, in Basin 11 is relatively low (19%). Table 11.2 shows the pipe compilation by size and material. The majority of the system is 24-inch or greater but is limited in capacity due to insufficient slopes. A preliminary recommendation is to remove any trunk lines with piping less than 12-inches in diameter and replace with a minimum of 18-inch diameter pipe, to provide additional capacity of the system.

Pipe Material: Basin 11 is comprised of five modeled material types: concrete, CMP, PVC, HDPE and ductile iron. The majority of the system (91%) consists of CMP and PVC, and the remaining 9% comprised of concrete, HDPE and ductile iron. PVC has a relatively low Manning's coefficient (0.011). In contrast, CMP pipe has a high Manning's Coefficient (0.024) which reduces the flow capacity to half that of PVC or HDPE, for the same slope. Material such as HDPE, smooth wall interior, is flexible and has a Manning's value similar to PVC (0.012). However, in contrast to PVC, HDPE has corrugated outer walls which allow it to lock into position in the ground and become less susceptible to movement and separation. In addition, the projected life expectancy of HDPE is in excess of 100 years. Material such as HDPE is more flexible and less likely to degrade overtime, and for this reason it is recommended replacement of CMP pipe be completed with HDPE.

System Maintenance: The final contributing issue to the City of Kelso Basin 11 storm water system is maintenance. During the inventory of structures and pipes, several notes were made in regards to cleaning a structure or pipe connection. Cleaning of a structure took place where needed to obtain existing data, and it is recommended the system continue to be cleaned on an annual or semi-annual basis to maintain the function of the system until recommended improvements can be made.

RECOMMENDATIONS

System Replacements: It is recommended at a minimum that the main pipes down Three Rivers Mall Drive (considered trunk line pipes) be replaced with HDPE pipe in the diameter size listed in Table 11.3. This would allow for increased pipe capacity and act as storage for the system should downstream tail-water conditions occur. Many of the smaller lines in the system are connecting into the trunk line and do not appear to be causing a significant problem to the system. However, it is recommended that any new or replaced pipe be composed of HDPE at a minimum diameter of 12-inches.

Capital Improvements: The estimated budget to upgrade from the existing pipe sizes to the pipe sizes listed is approximately $916,000, as shown in Table 11.4. This cost is based on contracting the work to be done by other than City of Kelso forces.

Operation and Maintenance: A guideline for order of precedence for the CIP has been developed such that budget consideration can be included and is suggested as follows:

1. Clean catch basins and storm drain manholes;
2. Clean and television storm drain pipes to determine if blockages are encountered;
3. Replace concrete and clay pipes with HDPE pipe such as ADS N-12 or similar;
4. Upgrade storm drain pipes on trunk lines to sizes recommended to handle flow from side systems and to provide additional storage during larger storm events;
5. Upgrade storm drain pipes on side streets to sizes recommended, and eliminate as many blind connections as possible during the improvement process.

These recommendations are based on a planning level assessment only. There may be physical constraints that make it impossible to install the large pipes recommended for upgrading the system. A detailed engineered design of the proposed system will be required, which takes into account the existing surrounding environment. The individual and overall system budget estimates have been developed based on the cost to remove and replace the pipes with the sizes as shown, and to repair the existing surface to its current condition. Consideration should be given to the shallow cover and other utilities within the City's right of way which may require additional engineering solutions and add unknown costs to those provided in this report.

Kelso Stormwater Management Plan
Phase II
Summary Legend

Legend

	System Flow > Pipe Capacity
	Ground elevation interpolated from nearest structure
	Invert elevation interpolated from upstream and downstream nodes
-0.02	Negative slope based on data provided
J	Junction
O	Outlet
Conc.	Concrete
T-cotta	Terracotta
DI	Ductile Iron
PVC	Polyvinyl Chloride
HDPE	High Density Polyethylene
CMP	Corrugated Metal Pipe
1000's	Catch Basins
4000's	Manholes or Curb Inlets
NDA	No Data Available

Basin 12

BASIN 12

SYSTEM ASSESSMENT

Basin Description: Basin 12 drains an area between Interstate 5 (I-5) to the east and Basin 13 to the west, from Lord Street to the north and Basin 11 to the south. It includes a portion of the Three Rivers Mall. Figure 12.1 shows an aerial photograph of Basin 12. Basin 12 outlets into a 60-inch pipe at node 4355 located along the eastern edge of the Three Rivers Mall property. The total drainage area for Basin 12 is approximately 90 acres. However, the area can be divided into two major sub-basins; the area north of Allen Street is approximately 40 acres and the area south of Allen Street is approximately 50 acres. The area to the north of Allen Street had insufficient field data to connect the existing pipes and structures to the system to the south. The topography suggests that the area to the north drain towards Allen Street either by overland flow or a combination of closed system piping and open channel flow. Therefore, this area was distributed equally to catch basins located along Allen Street (1104 through 1116) for the model. The land use for Basin 12 is approximately 48% single-family residential, 38% major retail, 8% special retail, 5% multi-family residential, and 1% open space. See Figure 12.2 for the land use area map of Basin 12.

System Modeling: Table 12.1 lists the structure information and connections, along with total flows and capacities. Figure 12.3 shows a schematic of the structure locations and piping layout. As stated in Chapter 2, junctions were entered into the model where blind connections were assumed to occur using the prefix J in the numbering system for easy identification. Field data for catch basins 1001-1004, 1196, 1198-1202 and manhole 4002 located in the area north of Allen Street had insufficient data to include in the model, as described above, and are not included in the system results. The runoff for this area of Basin 12 was divided equally into catch basins 1104 through 1116 using an area of 0.87 acres, a C value of 0.45 and a time of concentration of 15 minutes to distribute the flow from the north half of Basin 12 into the remainder of the basin.

Other assumptions were made in the modeling, such as interpolating an invert or rim elevation when junctions were added to the system using the prefix J in the numbering system for easy identification. In addition, the runoff from Basin 13 outfalls into Basin 12 at node 4029 and was accounted for in the model. This flow was entered into Basin 12 by entering the system CA and time of concentration at the outlet from Basin 13.

As seen in Table 12.1, 35% of pipes with insufficient capacity are less than 12-inch in diameter. Utilizing the current slopes, the majority of these pipes will gain capacity by upsizing to 12-inch HDPE pipe. Pipes P-12-100 and P-12-101 are 60-inch diameter and pipes P-12-102 through P-12-105 are 48-inch diameter, but have insufficient slope, and are undersized based on the modeled amount of flow in the system. Increasing these pipes from the existing to HDPE in the diameter listed in Table 12.3, keeping the same slope, will provide increased capacity in the system.

System Issues

Pipe size: The first system issue identified for Basin 12 is the presence of small diameter pipe, that is, pipe less than 12-inches in diameter. Approximately 30% of the system is comprised of pipe with a diameter less than 12-inches. Table 12.2 shows the pipe compilation by size and material. The small diameter pipe severely inhibits the capacity of the piping system due to the reduced flow capacity. A preliminary recommendation is to remove any trunk lines with piping less than 12-inches in diameter and replace with a minimum of 24-inch diameter pipe.

Pipe Material: Basin 12 is comprised of five modeled material types: concrete, CMP, PVC, HDPE and ductile iron, with only one 12-foot section of pipe consisting of ductile iron. The majority of the system (60%) consists of concrete, with 20% CMP and 20% PVC. Concrete and PVC have a relatively low Manning's coefficient (0.012 and 0.011, respectively). However, concrete piping is rigid material that provides movement only at the joints, and is susceptible to separation, fracture or breakage in the pipe if ground movement occurs. Typically, the most common failure in older concrete pipe occurs at the joints as the rubber gaskets become brittle and disintegrate, providing an opportunity

for the pipe to separate. Overtime, this can lead to deposit of unwanted material in the pipe and degradation or failure of the pipe. Material in the pipe opening blocks the path of flow for storm water, making it less effective. In contrast, CMP pipe has a high Manning's Coefficient which reduces the flow capacity to half of that of PVC or HDPE, for the same slope. Material such as HDPE, smooth wall interior, is flexible and has a Manning's value similar to PVC. However, in contrast to PVC, HDPE has corrugated outer walls which allow it to lock into position in the ground and become less susceptible to movement and separation. In addition, the life expectancy of concrete pipe is approximately 40-years versus HDPE which has a projected life span in excess of 100 years. Material such HDPE is more flexible and less likely to degrade overtime, and for this reason it is recommended that replacement of any concrete or CMP pipe be completed with HDPE.

System Maintenance: The final contributing issue to the City of Kelso Basin 12 storm water system is maintenance. During the inventory of structures and pipes, several notes were made in regards to cleaning a structure or pipe connection. Cleaning of a structure took place where needed to obtain existing data, and it is recommended the system continue to be cleaned on an annual or semi-annual basis to maintain the function of the system until recommended improvements can be made.

RECOMMENDATIONS

System Replacements: It is recommended at a minimum that the main pipes down Allen Street, 10th Avenue and Vine Street (considered trunk line pipes) be replaced with HDPE pipe in the diameter size listed in Table 12.3. This would allow for increased pipe capacity and act as storage for the system should downstream tail-water conditions occur. Many of the smaller lines in the system are connecting into the trunk line and do not appear to be causing a significant problem to the system. However, it is recommended that any new or replaced pipe be composed of HDPE at a minimum diameter of 12-inches.

Capital Improvements: The estimated budget to upgrade from the existing pipe sizes to the pipe sizes listed is approximately $1,000,000, as shown in Table 12.4. This cost is based on contracting the work to be done by other than City of Kelso forces.

Operation and Maintenance: A guideline for order of precedence for the CIP has been developed such that budget consideration can be included and is suggested as follows:

1. Clean catch basins and storm drain manholes;
2. Clean and television storm drain pipes to determine if blockages are encountered;
3. Replace concrete and clay pipes with HDPE pipe such as ADS N-12 or similar;
4. Upgrade storm drain pipes on trunk lines to sizes recommended to handle flow from side systems and to provide additional storage during larger storm events;
5. Upgrade storm drain pipes on side streets to sizes recommended, and eliminate as many blind connections as possible during the improvement process.

These recommendations are based on a planning level assessment only. There may be physical constraints that make it impossible to install the large pipes recommended for upgrading the system. A detailed engineered design of the proposed system will be required, which takes into account the existing surrounding environment. The individual and overall system budget estimates have been developed based on the cost to remove and replace the pipes with the sizes as shown, and to repair the existing surface to its current condition. Consideration should be given to the shallow cover and other utilities within the City's right of way which may require additional engineering solutions and add unknown costs to those provided in this report.

Basin 13

BASIN 13

SYSTEM ASSESSMENT

Basin Description: Basin 13 drains an area primarily from Pacific Avenue along the west boundary to 8th Avenue along the east and from Church Street along the north boundary to Vine Street along the south. Figure 13.1 shows an aerial photograph of Basin 13. The discharge from Basin 13 outlets to Basin 12 at node 4029 and was added to the model of Basin 12. The total drainage area for Basin 13 is 44 acres and the land use is approximately 37% multi-family residential, 31% special retail, 31% town center, and 1% single-family residential.

System Modeling: Table 13.1, system summary, lists the structure information and connections, along with total flows and capacities. Figure 13.3 shows a schematic of the structure locations and piping layout. As stated in Chapter 2, junctions were entered into the model where blind connections were assumed to occur using the prefix J in the numbering system for easy identification. Field data for catch basins 1058-1059 and manhole 4016 located along 7th Avenue between Church and Academy Street indicates these catch basins are connected into the system through 8-inch pipe running south in 7th Avenue. Since there was no other field data, it was assumed that this pipe connects to the system at a blind connection in Allen Street. There is a significant change in elevation between Church Street and Allen Street, creating some steep slopes as indicated in the modeling results. It is possible there is an existing drop structure in this area that was unable to be field located and further field investigation is required if a more accurate model in this area is desired.

Other assumptions were made in the modeling, such as interpolating an invert or rim elevation when junctions were added to the system. The field data for manhole 4022 located in Oak Street indicates there is a 24-inch pipe entering to the east that is unaccounted for. The upstream system is located on private property and was therefore

unable to be surveyed. It is recommended additional field investigation be performed to determine what additional structures are connected to the City's system at this location.

As seen in Table 13.1, 58% of the pipes have insufficient capacity, the majority of those pipes being concrete. Replacing these pipes from the existing material to HDPE in the diameter listed in Table 13.3, keeping the same slope, will provide the required capacity in the system.

SYSTEM ISSUES

Pipe size: One of the system issues identified for Basin 13 is the presence of smaller diameter pipes, i.e., pipe with a diameter less than 12-inches. Approximately 63% of the system is comprised of 4, 6, 8, or 10-inch pipe. Table 13.2 shows the pipe compilation by size and material. The small diameter pipe severely inhibits the capacity of the piping system due to the reduced flow capacity. For this reason it is recommended replacement of any trunk lines with piping less than 12-inches in diameter be replaced with a minimum of 12-inch diameter pipe.

Pipe Material: The primary system issue identified for Basin 13 is the amount of concrete pipe existing in the system. Basin 13 contains four modeled material types: concrete, PVC, HDPE and clay. The majority of the system (81%) consists of concrete and the remaining (19%) of HDPE, PVC, or clay. All of these types of pipe are similar in properties, with a relatively low Manning's coefficient ranging from 0.010 to 0.013. However, both concrete and clay piping are rigid materials that provide movement only at the joints, and are susceptible to separation, fracture or breakage in the pipe if ground movement occurs. Typically, the most common failure in older concrete pipe occurs at the joints as the rubber gaskets become brittle and disintegrate, providing an opportunity for the pipe to separate. Overtime, this can lead to deposit of unwanted material in the pipe and degradation or failure of the pipe. Material in the pipe opening blocks the path of flow for storm water, making it less effective. In addition, the life expectancy of concrete pipe is approximately 40-years versus HDPE which has a projected life span in excess of 100 years. Material such HDPE is more flexible and less likely to degrade

overtime; HDPE has a life expectancy of over 100 years. A preliminary recommendation is to replace any concrete or clay pipe with HDPE.

System Maintenance: The final contributing issue to the City of Kelso Basin 13 storm water system is maintenance. During the inventory of structures and pipes, several notes were made in regards to cleaning a structure or pipe connection. Where ever possible, the cleaning of a structure took place to obtain existing data, and it is recommended the system continue to be cleaned on an annual or semi-annual basis to maintain the function of the system until recommended upgrades can be completed.

RECOMMENDATIONS

System Replacements: It is recommended at a minimum the main pipes down 4th, 5th and 7th Avenues as well as Allen, Oak and Vine Streets (considered the main trunk line pipes) be replaced with HDPE pipe in the diameter size listed in Table 13.3. This would allow for increased pipe capacity and act as storage for the system should tail-water conditions occur downstream in Basin 12. Many of the smaller pipes that are connecting into the trunk line from side connections do not appear to be causing a significant problem to the system. However, it is recommended that any new or replaced pipe be composed of HDPE at a minimum diameter of 12-inches.

Capital Improvements: The estimated budget to upgrade from the existing pipe sizes to the pipe sizes listed is approximately $766,500, as shown in Table 13.4. This cost is based on contracting the work to be done by other than City of Kelso forces and includes the cost to repair the street surface to existing conditions.

Operation and Maintenance: A guideline for order of precedence for the CIP has been developed such that budget consideration can be included and is suggested as follows:

1. Clean catch basins and storm drain manholes;
2. Clean and television storm drain pipes to determine if blockages are encountered;
3. Replace concrete and clay pipes with HDPE pipe such as ADS N-12 or similar;

4. Upgrade storm drain pipes on trunk lines to sizes recommended to handle flow from side systems and to provide additional storage during larger storm events;
5. Upgrade storm drain pipes on side streets to sizes recommended, and eliminate as many blind connections as possible during the improvement process.

These recommendations are based on a planning level assessment only. There may be physical constraints that make it impossible to install the large pipes recommended for upgrading the system. A detailed engineered design of the proposed system will be required, which takes into account the existing surrounding environment. The individual and overall system budget estimates have been developed based on the cost to remove and replace the pipes with the sizes as shown, and to repair the existing surface to its current condition. Consideration should be given to the shallow cover and other utilities within the City's right of way which may require additional engineering solutions and add unknown costs to those provided in this report.

Appendix F

Basin 14

BASIN 14

SYSTEM ASSESSMENT

Basin Description: Basin 14 consists of the structures along Columbia Avenue, Crawford Avenue and Cowlitz Way, from 9th Street west to 1st Street. It drains an area between the bank of the Cowlitz River dike on the west and the east edge of 9th Street to the east, from Columbia Avenue to Cowlitz Way. Figure 14.1 shows an aerial photograph of Basin 14. It contains 84 structures (55 catch basin, 14 manholes and 15 assumed connections), the majority on Crawford Avenue and Cowlitz Way, and outlets into the Cowlitz River at node 8000. Structure 8001 contains a gate valve and a flapper valve. The total drainage area for Basin 14 is 30.82 acres and the land use is approximately 67% residential, 18% special retail, 7% open space, 4% multi-family residential, and 4% town center. See Figure 14.2 for the land use areas in Basin 14.

System Modeling: Table 14.1 lists the structure information and connections, along with total flows and capacities. Figure 14.3 shows a schematic of the structure locations and piping layout. As stated in Chapter 2, junctions were entered into the model where blind connections were assumed to occur using the prefix J in the numbering system for easy identification. Field data for catch basins 1032, 1034 and 1035 indicates these catch basins are connected into the system through a blind connection. However, as stated previously, blind connections cannot be modeled, and these catch basins were entered into the model as connecting into catch basin 1033, rather than creating three separate junctions in the same vicinity. The city should assume these pipes connect at 90-degrees to the main line pipe.

Other assumptions were made in the modeling, such as interpolating an invert or rim elevation when junctions were added to the system. The field data for manhole 4006 indicates that no pipes are entering this structure. However, catch basins 1009 through 1012 each had one pipe leaving the structure and heading toward manhole 4006. Again, for modeling purposes, these four catch basins were assumed to connect to the

interpolated invert of this manhole. It is recommended that additional investigation be performed to determine how these catch basins connect to the system.

As seen in Table 14.1, the majority of pipes with insufficient capacity (82%) are less than 12-inch in diameter. Utilizing the current slopes, the majority of pipes less than 12-inch in diameter will gain capacity by upsizing to 12-inch HDPE pipe. Pipes P-14-102 through P-14-105 and P-14-200 through P-14-204 have sufficient slope, but are undersized based on the modeled amount of flow in the system. Increasing these pipes from the existing to HDPE in the diameter listed in Table 14.3, keeping the same slope, will provide increased capacity in the system.

System Issues

Pipe size: The first system issue identified for Basin 14 is the presence of small diameter pipe, that is, pipe less than 12-inches in diameter. Approximately 77% of the system is comprised of pipe with a diameter less than 12-inches. Table 14.2 shows the pipe compilation by size and material. The small diameter pipe severely inhibits the capacity of the piping system due to the reduced flow capacity. A preliminary recommendation is to remove any trunk lines with piping less than 12-inches in diameter and replace with a minimum of 12-inch diameter pipe.

Pipe Material: Basin 14 is comprised of three modeled material types: concrete, PVC and clay, with only one 2-foot section of pipe consisting of PVC. The majority of the system (86%) consists of concrete and the remaining (14%) of clay. Both of these types of pipe are similar in properties, with a relatively low Manning's coefficient. However, both concrete and clay piping are rigid materials that provide movement only at the joints, and are susceptible to separation, fracture or breakage in the pipe if ground movement occurs. Typically, the most common failure in older concrete pipe occurs at the joints as the rubber gaskets become brittle and disintegrate, providing an opportunity for the pipe to separate. Overtime, this can lead to deposit of unwanted material in the pipe and degradation or failure of the pipe. Material in the pipe opening blocks the path of flow for storm water, making it less effective. In addition, the life expectancy of

concrete pipe is approximately 40-years versus HDPE which has a projected life span in excess of 100 years. Material such HDPE is more flexible and less likely to degrade overtime; HDPE has a life expectancy of over 100 years. For this reason it is recommended replacement of any concrete or clay pipe be completed with HDPE.

System Maintenance: The final contributing issue to the City of Kelso Basin 14 storm water system is maintenance. During the inventory of structures and pipes, several notes were made in regards to cleaning a structure or pipe connection. Cleaning of a structure took place where needed to obtain existing data, and it is recommended the system continue to be cleaned on an annual or semi-annual basis to maintain the function of the system until recommended improvements can be made.

RECOMMENDATIONS

System Replacements: It is recommended at a minimum that the main pipes down Crawford, Columbia, Cowlitz and Pacific Avenue (considered trunk line pipes) be replaced with HDPE pipe in the diameter size listed in Table 14.3. This would allow for increased pipe capacity and act as storage for the system should downstream tail-water conditions occur. Many of the smaller lines in the system are connecting into the trunk line and do not appear to be causing a significant problem to the system. However, it is recommended that any new or replaced pipe be composed of HDPE at a minimum diameter of 12-inches.

Capital Improvements: The estimated budget to upgrade from the existing pipe sizes to the pipe sizes listed is approximately $500,000, as shown in Table 14.4. This cost is based on contracting the work to be done by other than City of Kelso forces.

Operation and Maintenance: A guideline for order of precedence for the CIP has been developed such that budget consideration can be included and is suggested as follows:

1. Clean catch basins and storm drain manholes;
2. Clean and television storm drain pipes to determine if blockages are encountered;

3. Replace concrete and clay pipes with HDPE pipe such as ADS N-12 or similar;
4. Upgrade storm drain pipes on trunk lines to sizes recommended to handle flow from side systems and to provide additional storage during larger storm events;
5. Upgrade storm drain pipes on side streets to sizes recommended, and eliminate as many blind connections as possible during the improvement process.

These recommendations are based on a planning level assessment only. There may be physical constraints that make it impossible to install the large pipes recommended for upgrading the system. A detailed engineered design of the proposed system will be required, which takes into account the existing surrounding environment. The individual and overall system budget estimates have been developed based on the cost to remove and replace the pipes with the sizes as shown, and to repair the existing surface to its current condition. Consideration should be given to the shallow cover and other utilities within the City's right of way which may require additional engineering solutions and add unknown costs to those provided in this report.
